ABSTRACT
Due to a lack of quantitative studies that either support or refute the Pushed Output Hypothesis (Swain, 1985), the current study attempts to establish baseline quantitative data on the effectiveness of pushed output. Specifically, pushed output’s role in helping learners to acquire a receptive knowledge of new lexical items was compared with more traditional approaches to teaching new vocabulary words, namely, via classroom reading tasks (an input-based approach) and vocabulary activity worksheets (a task-based approach). In a carefully controlled pretest-posttest quasi-experimental study, 112 Japanese university students of English in four intact classes learned 10 new English vocabulary words via each of the three methods. Results indicated that regardless of the language level of the learner, significantly more words were learned by the Pushed-Output condition. A secondary finding was that the vocabulary size of the learner significantly influenced the amount of words learned in each condition. Pedagogic implications are discussed.
I would first like to thank my two major advisors, Drs. J.D. Brown and Kenneth Schaefer. In addition to his expert advice regarding experimental design and statistical analysis, Dr. Brown’s feedback on the early draft of this manuscript greatly helped to improve the final product. Dr. Schaefer has been a great source of support and encouragement through the often difficult process of completing this dissertation. It is no understatement to say that without his help and advice I would have never been able to finish.

Thanks are also due to Professor Paul Nation who was the person most responsible for inspiring me to get involved in the field of second language vocabulary acquisition. His positive and frank comments at the early stages of developing my experimental design, as well as the sharing of his vast library of resources on second language vocabulary research helped tremendously.

I am also greatly indebted to Sandy Fotos for serving on my dissertation committee and for providing so much encouragement and advice during the early stages of writing up this study.

CHAPTER 1
INTRODUCTION

Statement of the Problem

Although there seems to be a growing acceptance among SLA researchers that vocabulary is a crucial component of overall communicative competence (Schmitt and McCarthy, 1997), it is still an area that is often neglected both in and outside the classroom. Zimmerman (1997a) argues that “the teaching and learning of vocabulary has been undervalued in the field of second language acquisition (SLA) throughout its varying stages and up to the present day” (p. 5). Paribakht and Wesche (1997) point out that there still remains an enormous amount of research to be done in the area, as “it is still far from clear how learners acquire vocabulary or how it can best be taught” (p. 174).

In terms of pedagogy, if vocabulary is addressed at all in the ESL classroom, it is has traditionally been relegated to the role of incidental learning. Sokmen (1997) summarizes the way vocabulary has usually been handled:

For many of us, our perspective on the teaching of vocabulary was greatly influenced by the top-down, naturalistic approaches of the 1970s and 1980s. The emphasis was implicit, incidental learning of
vocabulary. We were taught the importance of directing L2 learners to recognize clues in context... Textbooks emphasized inferring word meaning from context as the primary vocabulary skill (p. 237).

Incidental learning of vocabulary has to a large extent, then, become the status quo. Even when vocabulary is taught more directly in the classroom, it tends to be via supplementary workbooks containing word manipulation exercises, rather than as a main element of the curriculum. Schmitt (2000) points out that these types of “approaches to vocabulary have unsurprisingly focused on activities for the explicit study of vocabulary” (p. 146). Indirect support for the popularity of this type of approach can be found by making a quick scan of ESL/EFL vocabulary books sold by major publishing houses such as Addison-Wesley, Cambridge University Press, or Heinle & Heinle. Not only are there no course books offered which have vocabulary as an organizing or main component of the syllabus, but the supplementary vocabulary books which are offered tend to be very similar in approach, introducing new words and definitions on one page, followed by a series of activities to give practice using the new words (for example, crossword puzzles, matching activities, word searches, fill in the blank, and the like). Current examples of this type of book include: the English Vocabulary in Use series (McCarthy, O’Dell, & Shaw 2001; Redman, 1997; Redman & Shaw, 1999; McCarthy,

The current study discusses the theoretical and methodological underpinnings of these two widely used techniques for teaching vocabulary, and then compares their effectiveness, with a third technique, learning vocabulary via simple writing tasks, which, although not widely used in the classroom for the past few decades, may actually be more representative of current thinking about the second language acquisition process, including Depth of Processing Theory (Craik & Lockhart, 1972), and the Pushed Output Hypothesis (Swain, 1985).
CHAPTER 2
REVIEW OF THE LITERATURE

The Role of Input in SLA

Although the theories and research of Stephen Krashen are by no means universally accepted, since the early 1980s, he has arguably influenced the debate on the role of input in SLA more than any other researcher. According to Krashen’s Input Hypothesis (Krashen & Terrel; 1983, Krashen, 1985), human beings acquire languages in only one way – by understanding messages, or by receiving “comprehensible input”. Learners progress along a natural order by understanding input that contains vocabulary and structures slightly above their current level of understanding (what Krashen calls “i + 1 input”). They are able to understand language that contains unacquired grammar and vocabulary through the help of contextual clues such as extra-linguistic information, knowledge of the world, and previously acquired competence.

Krashen (1985), strongly downplays the role of output or interaction with his claim that comprehensible input is both necessary and sufficient for language acquisition. He states that:
Speaking is the result of acquisition, not its cause. Speech cannot be taught directly, but emerges on its own as a result of building competence via comprehensible input (p. 2).

Although Krashen’s assertion that language production doesn’t play a role in language acquisition is a controversial one (Gregg, 1984; Sharwood-Smith 1986; Ellis, 1990), his claim that comprehensible input is an essential ingredient for acquisition seems to be widely accepted within the field of applied linguistics (Long 1983a; Swain, 1981; Brown, 1985; Ellis, 1985).

Extensive Reading

In the mid 80s, this belief that exposing learners to large quantities of comprehensible input was both necessary and sufficient to cause language acquisition was especially prevalent in the area of reading skills and vocabulary development. Krashen (1989) claimed that the most effective way for learners to acquire new vocabulary and develop their spelling ability is through exposure to large amounts of “comprehensible input” via extensive reading. Since free reading of materials that students like is also a low-anxiety activity, Krashen argues that such reading activities are the most efficient means by which a learner can acquire new vocabulary (Krashen 1989, 1993a & b).
His “Natural Approach” became the rallying cry of “learn to read by reading” (Smith, 1982). Reading proponents such as Nutall (1982, 1996), claimed that extensive reading programs were the most effective way of increasing vocabulary size, improving reading skills, and developing overall language ability. Studies, such as Robb and Susser’s (1989) comparison of extensive reading with a skill building approach, Hafiz and Tudor’s (1989) three month experimental study of extensive reading via graded readers, and Krashen’s (1988) discussion of free reading programs and student’s self reports of free reading all found that extensive reading worked at least as effectively as the methods it was compared with, and correlated well with success in reading comprehension.

Elley’s “book flood” studies (Elley & Mangubai, 1981, 1983) looked at the effect of a “book flood” of 250 high interest children’s books on 380 students, in comparison with a control group of 234 students over a 20 month period and found that the oral reading of children’s stories to elementary school children learning English as a second language led to large, long term gains in vocabulary (twice the rate of the control group).

More indirect support for Krashen’s Input Hypothesis can be found in Grabe and Stoller’s (1997) case study of
Grabe’s attempt to learn Portuguese primarily via extensive reading of materials that were of specific interest to the subject. One of the chief goals of the study was to “explore the extent to which extensive reading practice without formal instruction would promote reading ability and vocabulary development in Portuguese. The authors found that it was “clear that Bill made reasonably good progress learning to read with the primary input being through extensive reading…” (p. 113) The study also found that “reading and vocabulary are reciprocally causal... that reading improves vocabulary knowledge and vocabulary knowledge supports reading development” (p. 119), and that the study “strongly suggests that reading and vocabulary will develop as the result of extensive reading practice” (p. 119).

The net result of Krashen’s claims regarding the need for large amounts of comprehensible input, and the positive benefits of extensive reading, was that since the 1980s, extensive reading has became one of the most widely used methods for developing reading and vocabulary skills.

The Role of Interaction in SLA

Although not directly related to the three teaching methods employed in this experiment, a brief discussion of the theoretical role which interaction plays in SLA, as well
as the role of “foreigner talk”, which is discussed in this
and the subsequent section, is needed to provide a
historical context for the movement of researchers interest
in the role of input (condition 1 in
the experiment), to a growing interest in the role of output
(conditions three and four).

In a reaction to the perceived inadequacies of
Krashen’s theories regarding the role of input in SLA, an
increasing amount of research has been conducted on the
relationship between language use and acquisition. Hatch
(1978, Hatch, Flasher, & Hunt, 1986), and Long (1980, 1983a,
1983b, 1985) have proposed that learners and their
interlocutors negotiate the meaning of messages by modifying
and restructuring their interaction in order to reach mutual
understanding. As a result of this negotiation, learners
come to comprehend words and grammatical structures beyond
their current level of competence and ultimately incorporate
them in their own production. Long and others have claimed
that interactional modification is the chief mechanism that
brings about comprehension, and thus acquisition (Pica,
Young, & Doughty, 1987).

Hatch (1978), argues that what has been missing in the
research is an explanation of the process of second language
acquisition. She calls for a shift to discourse analysis
(conversation analysis in particular), studies of children
L1 acquisition, and SLA to answer the question of ‘how’ children learn language. She points out that:

It is not enough to look at input and to look at frequency; the important thing is to look at the corpus as a whole and examine the interactions that take place within conversations to see how the interaction itself determines frequency of forms and how it shows language functions evolving (p. 403).

The basic premise had long been that children start by learning basic syntactic structures; moving from one word phrases to two-word phrases, to more complex structures, eventually putting these structures together in order to carry on conversations with others. However, based on findings in the area of discourse analysis, Hatch argues that for both first language acquisition and second language acquisition, language learning evolves primarily from learning how to carry on conversations.

From an examination of evidence from studies of children acquiring first and/or second languages, Hatch complies a sequence of steps that children go through when talking to others. First, the child must get the attention of the adult, and identify a topic. The child then relies on the adult to help him build the conversation whenever he encounters any difficulties perceiving and nominating topics.
Adults often help by asking clarification questions. The child’s “conversation” is semantically linked (vertically) by the adults interaction (horizontal constructions). This then becomes a prototype for future syntactic development for the child.

The same process generally holds true for adult second language learners, although adults have more difficulty in understanding and nominating topics unless they know the necessary vocabulary (since adult discourse contains topics that are much more diverse and abstract). Adults also tend to rely upon their partners to build conversations. When clarifying or nominating a topic, adult learners often solicit vocabulary. Hatch feels that it is out of these interactions from which conversational ability develops, which in turn leads to language development.

The Importance of Redundancy in Input

Pica (1992, Pica, Young, & Doughty, 1987) conducted a study involving native-speaker (NS) – nonnative-speaker (NNS) interactions to measure what effects, if any, interactional modifications such as requests for clarification or confirmation, would have on comprehension. One group of learners received pre-modified sets of input (condition one), while the input for the second group was modified during the course of interaction (condition two). The mean score for
condition two learners was greater than for the condition one (88% vs. 69%, respectively). It was found that there were 50% more words per direction and twice as many occurrences of redundant input for condition two groups than for condition one. Furthermore, the condition two interactions tended to result in input that was more complex than input that was modified according to conventional criteria of linguistic simplification. Pica argues that it is redundancy of input that aids comprehension;

...it was believed that these moves may have been the mechanism that triggered the increase in repetitions and hence overall quantity of input, which helped subjects to comprehend the more difficult directions (pp. 750–751).

In a study of university students in Canada who were taking introductory psychology courses in an L2 (one group in English and another in French) where the language of instruction was the L1 of the instructor, Wesche and Ready (1985) found that in parallel situations, both instructors made systematic deviations from native-speaker speech in attempts to ensure that content was understood when addressing students. The main characteristics of these foreigner/teacher talk adjustments were: simplification, well-formedness (standard usage), explicitness, regularization, redundancy, and pragmatic grammar expectancy
(which was defined as gearing the form and content of the presentation to what the speaker thinks the learner’s expectancy system will be able to handle). The instructors used comprehension checks and non-verbal feedback from learners, as well as unsolicited feedback to fine tune adjustments at different points in the discourse.

L2 student performance in the course (they took the same exams as L1 students with L1 instructors), as well as an analysis of their regular meetings with language teachers concerning the psychology course work, provided indirect evidence that these adjustments aided second language acquisition. As in the Pica et al. Study (1987), Wesche and Ready (1985), credited redundancy with making modified input comprehensible, since

It goes beyond the linguistic code and adjustments made in surface forms of language and deals as well with semantic and non-verbal adjustments at other levels of communication behavior (p. 111).

The Role of “Foreigner Talk”

As these and other studies have shown, native speakers often make interactional modifications to assist learners with comprehension. These interactional features, as reported by Long in a discussion of his Interaction Hypothesis (1983b),
are; confirmation checks, comprehension checks, clarification requests, self-repetitions, other repetitions, and expansions. In the Wesche and Ready (1985) study of immersion students, one of the characterizations made of foreigner talk was “simplification”. Ellis (1985), however, argues that it may not be appropriate to conclude that input facilitates SLA due to the process of simplification. He cites a study by Scarcella and Higa (1981) which reports that children, who tend to receive simpler input than adolescent learners do, also tend to learn at a slower rate than adolescents:

They hypothesize that it is the negotiation that results from the adolescent learner’s more active involvement that contributes to their faster development. This involvement is manifest in the strategies they use to obtain native speaker explanations for just those parts they do not understand and the extra work they do in sustaining discourse (p. 82).

Thus, a complete picture of how input is made comprehensible cannot be obtained simply by counting up the number of native speaker adjustments. Ellis (1992), argues that comprehensible input needs to be understood in terms of “the mutuality of understanding between interactants rather than in terms of simplified input” (p. 33).
The Interaction Hypothesis

While it has not yet been empirically established that comprehension causes acquisition, Long’s (1983a) Interaction Hypothesis seems to rely on a variety of studies which suggest that the interactional modifications which take place during conversation assist comprehension of input. He argues that increases in input translate into increases in the amount of negotiation. This, in turn, increases the number of repetitions in the input, which ultimately helps learners to comprehend. Support for this position can also be drawn from Seliger’s (1983) “high input generators”, who showed a significant correlation between quantity of interaction in the classroom and achievement scores received at the end of the course.

If increases in the amount of input is beneficial to SLA, what about the quality of input? Is input from other learners less beneficial that input from native-speakers? Will they learn mistakes from each other? Porter (1986) found that, while learners cannot provide each other with the accurate grammatical and sociolinguistic input that native-speakers can, learners can offer genuine communicative practice, including opportunities for negotiation of meaning. Porter’s study showed that there were similarities in the repairs and prompting by native-
speakers, and the repairs and promptings of advanced and intermediate learners. Input from L2 learners was also found to be as comprehensible as NS input. Learners did not pick up each others mistakes, nor did they miscorrect each other. Slightly different results were obtained in Wong-Filmore’s (1982) study of sixty kindergarten L2 learners. Here, it was found that classrooms which provide more comprehensible input and opportunities for students to negotiate meaning with the teacher and native speaking children, did better than classrooms where there was L2 student to student interaction.

The Role of Output in SLA

Although the Interaction Hypothesis received a great deal of attention, the results of a 10 month longitudinal study of two Vietnamese students conducted by Sato (1986), seems to call into question Long’s claim that conversational interaction facilitates language acquisition. Her analysis of the two learner’s interlanguage development within the specific semantic domain of past time reference (PTR) reveals that while conversational interaction did seem to facilitate communicative performance, there was no clear evidence that these interactions facilitated acquisition of all of the linguistic devices which encode PTR.
Despite a general agreement among researchers that comprehensible input is an essential element of SLA, most now maintain that it is not sufficient. Swain’s observational data of the French immersion program in Canada (Allen, Swain, Harley, & Cummins, 1990) notes that although students received large amounts of “comprehensible input” over a period of many years, with many corresponding opportunities for “interaction” as Long defines it, few ever exhibited a full mastery of French.

The researchers noted that most classes tended to be quite teacher-centered with students giving only short answers to teacher questions (less that 14% of students’ classroom utterances were more than a phrase in length). Swain argues that part of the problem was that these learners had had little opportunity to engage in two-way negotiated exchanges in the classroom. She hypothesized that in order for students to achieve full competence, their linguistic resources needed to be stretched. What was missing was “comprehensible output”. Swain (1985) points out that:

To achieve native-speaker competence, the meaning of ‘negotiating meaning’ needs to be extended beyond that usual sense of simply ‘getting one’s message across’. Simply getting one’s message across can and does occur
with grammatically deviant forms and sociolinguistically inappropriate language (p. 248).

According to Swain, negotiating meaning needs to incorporate the notion of being ‘pushed’ toward the delivery of a message that is not only conveyed, but conveyed precisely, coherently, and appropriately. Swain (1995a) argues that this act of “pushing” leads learners to make more of an effort, to “stretch” their interlangauge resources, which forces them to process language more deeply, and helps them to move beyond their current stage of language development.

Since Swain first proposed the Pushed Output Hypothesis in 1985, several qualitative studies have given it qualified support. Pica, Holliday, Lewis, and Morgenthaler (1989), for example, found that in response to requests for clarification or confirmation, learners tended to modify their output. Although the study did not show that these conversational modifications specifically led to acquisition, one of the assumptions of the Output Hypothesis is that such modifications contribute to the process of SLA.

Kowal and Swain (1997), observed students working on three different types of collaborative tasks (dictagloss, cloze, and proof-reading) in a French immersion program, and found evidence of students “noticing the gap” between what
they wanted to say and what they were able to say. As
predicted by the Output Hypothesis, this happened primarily
as students were “pushed” to produce the target language.

In an exploratory study involving six learners in a
two-way information gap task with the researcher (three
experimental and three control), Nobuyoshi and Ellis (1993)
found evidence which suggests that pushing learners to
produce output leads to better acquisition. Experimental
subjects were asked for clarification requests by the
researcher each time they produced an utterance that
contained a past tense error, while the control group was
not. One week later, two of the three experimental subjects
showed improvement in their use of the past tense, while no
improvement was shown by any of the control subjects.

Swain and Lapkin (1995), looked at 18 students from an
eighth grade early French immersion class who were trained
to use think aloud procedures while writing and article for
a newspaper and found that as they were encouraged to
produce their L2, students noticed gaps in their linguistic
knowledge. Again, although the study did not specifically
show that noticing led to acquisition, the authors argue
that this type of noticing plays a consciousness-raising
function which trigger cognitive processes such as
hypothesis testing about how the L2 works, which have
already been implicated in previous studies of second
language learning (Swain, 1995b; Selinker, 1972; Corder 1981).

Due to their focus on acquisition of advanced grammatical structures via collaborative tasks, most studies of pushed output have been qualitative in nature, yielding little quantitative evidence that pushed output enhances acquisition. The current study is an attempt to establish such quantitative data by focusing on the learning of new vocabulary words (rather than grammatical structures) which can be treated as discrete points in a statistical analysis, and operationalizing pushed output as something that can occur within an individual task.

The Depth of Processing Theory

The underlying mental processes which help pushed output to foster second language acquisition may be partially explained by studies of cognition and memory done in the early 1970s. In their seminal criticism of "multistore" approaches to explaining human memory, Craik and Lockhart (1972), proposed the Depth of Processing Theory. Until that time, most research had been concerned with the distinction between short-term and long-term memory (Broadbent, 1958; Waugh & Norman, 1965), with the assumption that the longer a new piece of information was held in short term memory, the better chance there was of it becoming part
of long term memory (Baddeley, 1966). Craik and Lockhart argued that the most important factor is actually the shallowness or depth by which a new piece of information is initially processed, a process related to attention. The authors point out that shallow, sensory levels of depth might be characterized by processing the stimuli simply in terms of its visual or acoustic properties, whereas deeper, more semantic levels of processing might involve analysis of meaning, compatibility with the analyzing structures, and processing time. In a subsequent article, Craik and Tulving (1975), expand upon this aspect of the theory:

Stimuli which do not receive full attention, and are analyzed only to a shallow sensory level, give rise to very transient memory traces. On the other hand, stimuli that are attended to, fully analyzed, and enriched by associations or images yield a deeper encoding of the event, and a longer lasting trace (p. 270).

Brown and Perry (1991) looked at three vocabulary learning strategies for ESL students that were differentiated according to Craik and Lockhart’s (1972) Depth of Processing Theory. Six intact classes at two levels of proficiency were divided into three treatment groups (keyword, semantic, and keyword-semantic), and then received four days of instruction. Results were consistent
with predictions made by the theory, with information processed at the semantic level being remembered better than information processed at the acoustic and visual level, and information that was processed at multiple levels (keyword-semantic) remembered best of all.

In an experiment that looked at short and long term retention of new vocabulary words for three types of classroom learning tasks, Hustijn and Laufer (Hustijn & Laufer 2001; Laufer & Hulstijn, 2001) propose the Involvement Load Hypothesis in an attempt to explain the higher retention rate for vocabulary learning tasks which required deeper levels of mental processing. Their model consists of three motivational-cognitive constructs: need, search and evaluation. Need refers to whether the motivation to complete a task is extrinsic or intrinsic, search to the attempt by the learner to find the meaning of a new word through dictionaries or other means, and evaluation to the learners attempt to compare how the new word will fit together with other word. Although time on task was vastly different for the three conditions in their experiment, Hulstijn and Laufer found that tasks with greater involvement loads (that is, deeper levels of processing) resulted in greater learning.

Learning Vocabulary via Classroom Tasks
As mentioned in the introduction, if vocabulary is addressed at all in the classroom, it is usually by word manipulation tasks such as crossword puzzles, word searches, matching activities and the like. In addition to the many classroom texts of this type offered by the major ESL publishing houses (for example, McCarthy, O’Dell, & Shaw 2001; Redman, 1999; Redman & Shaw, 1999; McCarthy, O’Dell & Shaw, 1997; Seal, 1997, 1990; Kirn, 1984; Keen, 1994; Broukal, 2001), there are also a number of books offered to instruct the teacher in such approaches (for example, Nation, 1994; Taylor, 1992; Allen, 1983).

Several research studies have been conducted to compare the effectiveness of such tasks. In an experiment designed to look at the role negotiation of meaning had in language acquisition, Newton (1995), examines the vocabulary gains made by an adult ESL learner while performing four communicative tasks. Although negotiation had the least affect on language acquisition of the four factors Newton examined, the study did have two important findings. First, that the actual use of the new vocabulary word in the process of completing the task was a good predictor of whether or not the word would be learned, and second, that the learners who made the greatest gains on the post-test were those who used the story vocabulary most generatively (that is in new contexts or structures).
Joe, (1995, 1998) looked at the effectiveness of read and retell tasks on the acquisition of unfamiliar vocabulary words and found that the degree of generation was closely related to learning. That is, when learners used the words in new ways or contexts they were more likely to remember the word on a variety of post-test measures.

Zimmerman (1997b), did a 10 week classroom-based study of the effect that L2 interactive vocabulary instruction would have on vocabulary gains. The experimental group received 3 hours per week of focused, interactive vocabulary instruction and were asked to do self-selected reading assignments, while the control group had the same self-selected reading assignment, but without the addition vocabulary instruction. Although it may not be surprising that the experimental group made greater vocabulary gains than the control group, considering the much greater amount of instruction the experimental group received, one interesting result was that the experimental group completed 50% more required reading than the control group which may indicate that the additional vocabulary instruction helped to make the reading assignments easier to understand and increased student motivation to read more.

Hall, (1992), compared the effects of learning mathematics vocabulary via split-information tasks with that of teacher-fronted learning and individual study. Although
all groups made vocabulary gains, results indicated that learners in the split-information condition made significantly more gains than the other two conditions. Interestingly, Hall found that there was only a low correlation (.36) between number of exposure to the word and the learning of the word, while there was a much higher correlation (.93) between learning and the number of times learners actually used the words in ways that were more generative, not just repetitions of the way the word was presented in the input.

Vocabulary Size and SLA

In an article titled “The Mathematics of Language,” Kucera (1982), points out that human language exhibits the somewhat contradictory characteristics of both efficiency and redundancy. For example, the English language is redundant in the sense that it has a only a limited number of permissible phonemes (33), as well as strict rules on what phonemes can occur together to form words (i.e., trip but not tlip). It is also extremely efficient in the sense that the vast majority of high frequency words are very short - 57% of the words in the one million word Brown Corpus (Kucera, 1982), are four or fewer letters, while the repeat-rate for long words is extremely low - "for every occurrence of a ten-letter word there are eight occurrences of a three-letter word, and for every occurrence of a
twenty-letter word there are 3,524 occurrences of a three-letter word (Kucera, 1982, p. 39).

The results of the numerous corpus-based word frequency studies done over the past few decades (Thorndike & Lorge, 1944; West, 1953; Kucera, 1982; Johansson & Hofland, 1989), reveal that this efficiency goes beyond word length alone. Despite research which estimates that the average 18 year old native English speaker has a vocabulary of somewhere between 16,000 (D’Anna, Zechmeister, & Hall, 1991) and 40,000 words (Nagy & Anderson, 1984), and the enormous total amount of words in the English language (there are 128,000 words, for example, in a large Webster’s dictionary), the most frequent words in the English language account for a disproportionate amount of the total number of running words readers encounter on a typical page of written text.

Table 1 summarizes the findings of Nation (1990), which is based on his own research on acquisition of technical vocabulary and vocabulary in university settings, as well as West’s (1953) General Service List. According to these figures, knowledge of just the 1000 most frequent words in the English language (less than 1% of the words appearing in the Webster’s dictionary) would allow a reader to understand approximately 75% of the words appearing on a page of text. Similar findings have been reported in Engels (1968), and Johansson and Hofland (1989). If readers know an additional
1000 words the percentage of coverage jumps to an impressive 87%.

Nation (1990), also found that a small number of additional words beyond the first 2000 occurs quite frequently within the genre of academia. Referred to in the literature as the "University Word List", knowledge of just these additional 836 words gives learners understanding of about 8% more words on the page, for a total of 95%. Nation (1990), and others (for example, see Marshall & Gilmour 1993), have demonstrated that within specific technical fields, certain words occur quite frequently, and that mastery of the 1000-2000 specialized words associated with that field can give the learner an additional 2-3% coverage.
Vocabulary Size and Reading Ability

The importance of these frequency figures and the high percentage of coverage of running words that they offer becomes clear as one considers the close relationship between lexical knowledge and reading ability, as well as the growing body of research on how many words a non-native speaker needs to know to interact effectively with unsimplified texts. Chall (1987), for example, found that student scores on vocabulary measures were so highly correlated with reading comprehension scores, that reading vocabulary quizzes could be substituted for paragraph meaning tests.

Although classroom teachers often hear complaints of student’s over-reliance on dictionaries along with the admonishment that they need to learn to guess meaning from context, Marshall and Gilmour’s (1993) study of the relationship between lexical knowledge and reading ability in ESP students found that top down reading skills such as schema activation clearly depended on students already having a large vocabulary.

In an analysis of the readability and lexical load of the top three selling Japanese high school ESL reading textbooks, Browne (1998) found that student’s over reliance on dictionaries and translations may be partially explained by
the extremely high lexical load of the texts, which were often found to be even more difficult than typical native speaker texts.

In a study to determine what kind of threshold score was needed on the Cambridge First Certificate Exam before students could be said to be able to comprehend academic texts, Laufer and Sim (1985) found that the language base needed for students to be able to guess meaning from context was largely lexical in nature, outranking both knowledge of subject matter as well as syntactic structure.

Hirsch and Nation (1992), in their study of three short, unsimplified children’s novels found that a knowledge of the most frequent 2000 words from West’s (1953) General Service List gave the reader coverage of about 90% of the running words in the text. The authors point out, however, that this would still leave the reader with one out of every ten words as unknown, and cite research by Laufer (1989), and Liu and Nation (1985), which shows that about 95% coverage of text is necessary for students to be able to reach an acceptable level of reading comprehension, and to be able to guess meaning from context.

In an experiment designed to look at the effect of reading purpose on incidental word learning, Swanborn and de Glopper (2002), found that readers focused on text
comprehension learned significantly more words than those who read to learn about the topic or read for pleasure. An important secondary finding of specific relevance to the current study is that vocabulary size was a significant factor in all conditions, with higher ability students consistently outperforming low ability students.

Laufer’s (1992a) study, titled “How much lexis is necessary for reading comprehension,” found that the minimum lexical threshold at which there were more readers than non-readers (operationalized as those students who receiving passing scores on the two standardized reading tests used in the experiment) was 3000 words. This threshold also marked the level at which students who were proficient readers in their L1 were able to transfer their reading strategies to the L2. A follow-up study done by Laufer (1992b), which looked at how L2 reading was affected by lexical knowledge and general academic ability, found that students with a vocabulary size of less than 3000 word families could not read well irrespective of their academic ability, and similarly, that students with vocabulary sizes of 5000 or larger could read well in their L2 regardless of their academic ability.

All of the above studies highlight the importance of student knowledge of the most frequent several thousand words in the English language. Non-familiarity with these
words almost assures that students will not be able to use top down skills, activate schema, guess from context, score well on reading exams, or develop reading fluency. This implies that different types of learning activities could vary in their effectiveness according to the size of a learners’ vocabulary. For this reason, the current study will examine lexical size as an additional independent variable.

Input Frequency and Vocabulary Learning

There are a number of studies which have looked at the relationship between the number of times a word occurs in the input, and the likelihood that the word will be learned, all of which have the not surprising conclusion that providing more encounters with the word increases the chance that it will be learned. Palmberg’s (1987) study of beginning ESL students in Sweden, found that learners were more likely to remember words from the textbook which occurred most often. Elley and Mangubai’s “book flood” studies (Elley & Mangubai, 1981, 1983; Elley, 1989, 1991), found that a vocabulary word’s frequency of occurrence in the input was the factor which had the highest correlation with the vocabulary gains made by the elementary school children he was studying. Sokmen (1997), in a review of current trends in teaching second language vocabulary, argues that providing a number of encounters with new words
increases the likelihood that the word will be learned. Kachroo (1962) studied the relationship between the number of times a word occurred in a course textbook and found that words with multiple repetitions were the most likely to be learned by students, and words which only occurred once or twice were not known by more than half of the learners.

A study conducted by Saragi, Nation and Meister (1978), found that if words were encountered six or more times, they were learned by over 93% of the learners. Nation and Wang (1999) found that at least 10 exposures were necessary before a word could be considered a candidate for acquisition, though even this many encounters was no guarantee that a word would be learned. Zahar, Cobb, and Spada (2001), however, in a review of several such studies which suggest that vocabulary acquisition through extensive reading is very inefficient, with learners typically unable to identify more than 1/14 words tested. They argue that frequency needs are related to learner level, with lower level learners needing more encounters for learning to occur.

Statement of Purpose
Due to a lack of quantitative studies that either support or refute the Pushed Output Hypothesis (Swain, 1985), the current study was developed to establish quantitative baseline date on the effectiveness of pushed output in helping learners to acquire receptive knowledge of new
lexical items in comparison with more traditional approaches to teaching new vocabulary words, namely, via classroom reading tasks (input-based approach) and via vocabulary activity worksheets.

The specific research questions for this study were as follows:

1. Do vocabulary learning activities which require pushed output help students to learn more new words than input-based or activity-based vocabulary learning activities?

2. Is there a differential effect for the vocabulary size of the learner as to which type of vocabulary learning activity is most effective?

Stated in terms of variables, the dependent variable in this design is short-term vocabulary learning (as measured by a post-treatment vocabulary quiz), while the independent variables are task type (input, output or task-based), and learner level (large or small vocabulary size).

These research questions were tested through a quasi-experimental research experiment using a nonrandomized control group, pretest-posttest design. An overview of the research design, which was conducted over a three week
period between January and February of 1999, follows in the next section.
CHAPTER 3
METHODOLOGY

Participants

The participants for the main study were 109 Japanese EFL students in four intact classes at Aoyama Gakuin University, a four-year, private, Christian university in Tokyo, Japan. These classes consisted of two freshman oral English classes, one sophomore reading skills class and one junior reading skills class that the researcher was teaching during the 1998-1999 school year. Students in all four classes were non-English majors, studying in a department of business administration. About 70% were male, with an age range from 18-20 years old. Since one of the key research questions in this design relates to variability due to language ability and vocabulary size, no attempt was made to control the age or proficiency level of the learners in each class. In fact, as the data in the results section will reveal, despite some surface similarities, each class displays tremendous variation in the English language ability of its students.

Although it was not possible to get permission to conduct the experiment in classes other than those that were taught by the researcher, I was able to obtain permission to pilot all of the major instruments used in this study with a
group of 33 students from a colleague’s junior reading skills class (one that was similar in size and level to reading skills class in the main study.

The university has approximately 20,000 students attending both undergraduate and graduate programs spread equally between its two urban campuses. It is prestigious, private Christian university, consistently ranked as one of the top 10 private schools in the country. As such, the university has, throughout its history, placed a very strong emphasis on English education, with the result that even students not majoring in English, such as the ones who participated in this study, often displaying English skills higher than their peers at other universities.

All English classes in this department meet once a week for 90 minutes, for a total of either 23 or 24 classes per academic year (depending on the day of week the class meets, and the number of holidays which occur on that particular day of the week). Students in each of the four classes were randomly assigned one of the four treatments.

Materials

The research experiment presented in this paper makes use of the following materials:
1. The *Vocabulary Levels Test* (Nation, 1990), to establish learner’s overall vocabulary size.

2. A vocabulary checklist pretest to establish that the 10 new vocabulary words are unknown to the students before treatment.

3. A list of the 10 unknown treatment words with definitions given in both Japanese and English. This list is handed out to all three treatment groups before they begin their respective tasks.

4. A reading task that introduces the 10 new vocabulary words in the context of the reading.

5. A vocabulary activities task that gives the learners practice in using the 10 new words via typical vocabulary tasks such as crossword puzzles, matching activities, and word searches.

6. A writing task that asks the students to use each of the new words in at least two complete sentences.

7. Similar to number six (above), this writing task asks the students to use each of the new words in at least two complete sentences, but also provides one example usage sentence for each target word.
8. A 10 word, multiple-choice post-treatment quiz for establishing short term vocabulary retention

Each of these will now be discussed in more detail.

1. Vocabulary Level Test

Nation’s (1990) Vocabulary Levels Test was used to establish the approximate overall vocabulary size of each learner who took part in the experiment. This additional measure was taken since there is a possibility of a differential effect due to the size of a learner’s vocabulary as to which of the three learning techniques would be most effective.

The two major techniques for assessing vocabulary size are to either make a test based on random sampling from a dictionary, or to make a test based on a frequency list derived from a corpus (Nation, 2001). The Vocabulary Levels Test, an example of the latter, was chosen because it was felt that having specific information about a student’s knowledge of vocabulary at each of several different vocabulary frequency levels might be able to yield more useful information than having just the one overall vocabulary size number which would be generated by the dictionary random sampling technique.
The Vocabulary Levels Test is based on a list of high frequency words known as the General Service List (West, 1953), which was derived from a large corpus of approximately five million words. Results from the test gives information about learner knowledge of vocabulary words at the 1000, 2000, 5000, and 10,000 word levels, as well as about their knowledge of specialized academic vocabulary. At each of the five levels, the test gives students six blocks of six words – in each block, three of the words must be matched with three definitions. In this way, 36 randomly selected words from each level can be tested, even though only 18 words are matched. Table 2 gives an example of one six word block taken from the 2000 word level:

Table 2: Sample Item from the Vocabulary Levels Test

<p>| | | |</p>
<table>

<td></td>
</tr>
<tr>
<td>6. total</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Since only 18 words need to be matched at each level (for a total of 90 questions), the test is quick and easy to administer, requiring only about 45 minutes of class time.

Reported reliability studies on the Levels Test have been quite high: .94 in Read’s (1988) report of its use as a diagnostic pre-test and achievement post test in an intensive English course, and .97 in a report of its use as a norm-referenced instrument to measure the vocabulary size of Japanese employees at major multinational corporations (Beglar & Hunt, 1999).

2. Vocabulary checklist pretest

This type of vocabulary test, also known as the “yes/no test” (Read, 1997), was used to establish that the 10 new vocabulary words were unknown to the students before the treatment. In this type of test, students are simply presented with a list of words (no definitions are given) and asked to check off the words they know.

The yes/no test was chosen over other vocabulary tests where learners are asked to match words to definitions, in order to control for the possibility that some learning could occur due to taking a pre-test where information about the target words is given. Although yes/no tests have a long history in L1 and L2 vocabulary research (Nation, 1990,
cites studies of the yes/no test from as early as 1929 by
Sims, and a 1941 study by Bear & Odbert), one of the chief
criticisms of the test has always been that there is no way
to control for students over-reporting their vocabulary
knowledge by checking off words that they didn’t really know.

Anderson and Freebody (1983) came up with an ingenious
technique for addressing this possibility, by adding a
number of plausible non-words to the checklist. Through the
use of simple statistical procedures the validity and
reliability of the test could be calculated by adjusting the
numbers downward as learners reported false positives (i.e.,
when they placed a check next to a non-word). This study, as
well as subsequent studies by Meara (1990, 1991) and Meara
and Buxton (1987), have reported very high reliability
coefficients for the test.

3. A list of the 10 unknown treatment words with
definitions given in both Japanese and English.

Having taught English to students in this department
for several years, it would not have been difficult to
develop a list of 10 words unknown to the learners.
Unfortunately, it would be next to impossible to find an
authentic text of appropriate length which would contain all
10 these words for use with the students in the group who
would be learning the words via extensive reading.
Therefore, it was thought that the best solution would be to first find an appropriate reading passage, and then choose the list of 10 unknown treatment words from the passage itself.

Once the reading was chosen (the reading is discussed in more detail in the following section), I worked with another of the university’s native English teachers to develop a list of 48 words from the passage which we thought might be unknown to at least some of the learners. This list was then distributed to one of my classes not involved in the experiment (24 third year students in a reading class identical to one of the ones used in the experiment), and the students were asked to place an “X” next to any of the words they did not know. The 10 words that had the highest number of “X”s, were then chosen as the target words. A one-page sheet, which gave simple definitions for the words in both English and Japanese, was then developed with the help of a Japanese teacher of English. This list is handed out to all three treatment groups before they begin their respective tasks.

4. A reading task which introduces the 10 new vocabulary words in the context of the reading.

The reading, “Seasonal Marketing and Timing New Product Introductions” (Radas & Shugan, 1998), was chosen because it
was an authentic text from a marketing journal that had been scheduled to be used in one of our department’s intermediate-level marketing course. A variety of studies have pointed out that learners are far more likely to be motivated to read a passage related to their major than one that is not (for example, Elley & Mangubai, 1981).

Learning vocabulary via a reading task is usually considered "incidental learning" since the main focus of the activity is not on the learning of new vocabulary words. Most research in this area shows, however, that a single exposure to a new word in such an activity is generally not enough to guarantee acquisition of that word (Meara, 1980; Beck, McKeown, & Omanson, 1987).

Other studies have shown that when the task has been modified to either increase the number of exposures to the word in a single passage, or that attention is drawn to the word in some way such as underlining or glossing (Hulstijn, Hollander, & Greidanus, 1996; Watanabe, 1997), the chance that learners will acquire knowledge about the target word is enhanced. Therefore, the passage containing the 10 target words was rewritten so that each target word occurred at least two to three times. In order to draw learners’ attention to the target words, every occurrence of each of the target words in the passage was also underlined.
5. A vocabulary activities task that gives the learners practice in using the 10 new words via typical vocabulary tasks such as crossword puzzles, matching activities, and word searches.

There are a great variety of ESL/EFL textbooks on the market that contain vocabulary exercises. After reviewing a number of them, several of the more frequently appearing exercises were adopted for use in this task. In order to control for time on task, the exercises were first piloted on a small group of learners in another class not involved in the experiment. After one or two trial runs, it was found that three vocabulary exercises were needed to approximate the same amount of time used in the extensive reading condition.

6. A writing task that asks the students to use each of the new words in at least two complete sentences.

This (deceptively) simple task requires students to write two complete sentences in English using each of the 10 target words. The reason two sentences were required is twofold: First, since this was the “pushed output” condition, it was thought that two sentences would require more thought and effort than one sentence. Second, when piloting the task it was found that the time students were on task was much shorter than in the first two conditions – adding the
requirement of writing a second sentence evened out the amount of time needed to complete the task.

7. Similar to number six (above), this writing task asks the students to use each of the new words in at least two complete sentences, but also provides one example usage sentence for each target word.

This condition was added almost as an afterthought. As the time drew near for actually conducting the experiment on my students I found myself growing worried that the sentence writing task (without example sentences) would be far too difficult for my students to be able to complete. Past experience with giving students writing assignments taught me that Japanese EFL students tend to rely quite heavily on their dictionaries, which invariably provided them with sample sentences containing the word in question. It was felt that giving a sample sentence for each of the new treatment words would make the task easier for them to complete. For this particular writing condition, an additional reason that two, rather than one sentences were required was to make it more difficult for students to write their sentences simply by making a slight modification of the sample sentence.

Although a variety of vocabulary tests which give more detailed information about students depth of knowledge on individual words were available, a multiple choice format was chosen for this experiment since this type of test is more sensitive to small gains in vocabulary knowledge. The reliability of the post-test was calculated using a KR-20 analysis, with a resulting figure of .68.

Procedure

Protocol Development

The purpose of the pilot study, which was conducted between November of 1998 and January of 1999, was to develop and test the major instruments to be used in the experiment: (a) a reading passage and accompanying comprehension questions of approximately 30 minutes in length which contain the 10 treatment words and would be of interest to the Business Administration students in my department, (b) to develop activities for the other two conditions (activity-based and pushed output) which would require a similar amount of time for students to complete, and (c) to develop a "Yes-No" vocabulary pre-test for the ten treatment words. As was mentioned in the previous section, the 33 students who participated in the development and piloting of the instruments (13 in the initial development stage, and 20
in the actual pilot), were all juniors in a reading skills class taught by a colleague.

1. Development of the reading passage

The reading passage was initially trialed with three third year students from one of my colleague’s classes. It took between 45 to 57 minutes for them to read the passage and complete the comprehension questions, and all three reported that the passage was a bit hard for them as there “were too many difficult words” and too many “long sentences”.

The passage was then shortened and simplified by rewriting longer sentences into shorter ones, using simpler grammatical structures, and, where possible, omitting difficult, low frequency vocabulary words (excluding, of course, the target words), and replacing them with high frequency words that the students were more likely to know.

As can be seen in Table 3, when the activity was piloted several weeks later with seven other students from the same class, the task took much less time, about 30 minutes, with all seven students reporting that the task was not overly difficult for them.

</tr>
</tbody>
</table>

2. Development of activity and writing tasks

Since I wanted to remove time on task as a confounding variable, 30 minutes then became the target for the other two conditions. The first version of the vocabulary activity condition used four different tasks, but when trialed with two third year students, it was found that the tasks took approximately 38 minutes to complete, considerably longer than the goal of 30 minutes. The activity was then run again, after decreasing the number of tasks from four to three. The first attempt at three tasks resulted in a time of 33:38 (trialed with just one student), and on the second attempt, with a different combination of three tasks, a more acceptable time of 30:56 (again, with one student) was achieved. A similar result of 29:39 (see Table 3) was obtained when the trial was run with more students in the “official” trial.
For the writing condition, it was found that if only once sentence was required for each of the target words, only about 19 minutes was needed to complete the task. When the requirement was raised to two sentences for each target word, however, the amount of time needed to complete the task became very close to the other two conditions, with an average time of 32:42 (reported in Table 3).

3. Development of the yes-no pre-test

Although an unofficial pilot was run with several students in order to choose 10 target words from the reading passage that would be unknown to the population, it was felt that there would be less chance of difficulties later on if the yes-no test were given another trial run with a larger group of learners from a similar population. Thus, the yes-no test was given to the same group of 20 students that the three types of tasks were piloted on. The test was given before the learners received the tasks in order to gauge their knowledge of the words before any opportunities for learning took place.

Since it is desirable for the student’s score on the post-treatment vocabulary quiz to be attributable entirely to the treatment (and not to previous knowledge of the words), the best possible result on the yes-no test would be
that all 20 students reported that they knew none of the
target words, and that they would also not report knowing
any of the nonsense words (i.e., they were telling the truth
on their yes/no answers).

Unfortunately, as can be seen in Table 4, the results
for the pilot were not this clear cut. While 11/20 students
(55%) reported knowing none of the target words and none of
the nonsense words, another nine students reported knowing
at least one or more of the nonsense words. If we allow for
a margin of error and include students with only one or two
false positives (the number of nonsense words they report
knowing), the number of students who report knowing none of
the target words grows to 15 students (75%).

</table>

Although it is worrisome that one student reports knowing 6/10 of the target words, and another student 4/10, it can be argued that their responses are unreliable, since it is likely that the extremely high number of false positives they have (4/5 or 80%), are the result of random guessing, or rushing through the exam and checking “yes” for every word.

If, then, we consider these students to be outliers that should be excluded from analysis, the results seem more
positive and clear. 15/18 students (83%) know none of the target words, and 17/18 (94%) know two target words or less. This seems to indicate that the 10 target words are unknown to the large majority of the population studied, strengthening the claim that much of their score on a post-treatment vocabulary quiz will be due to the effects of the treatment, rather than a prior knowledge of the words.

Experiment

The experiment, which took place over a two-week period in January of 1999, was conducted as follows:

Detailed Overview of Experimental Procedures

Class 1: (5 min.) Explain experiment
(5 min.) Pass out Levels Test/give directions
(45 min.) Conduct Levels Test
(5 min.) Collect papers
(30 min.) Regular class activities

Class 2: (5 min.) Explain experiment
(5 min.) Pass out Yes-No Test/give directions
(10 min.) Conduct Yes-No test
(5 min.) Collect papers
(10 min.) Pass out new vocabulary & treatments/give directions
(30 min.) Conduct four treatments
(5 min.) Collect papers
(5 min.) Pass out Post-test/give directions
(10 min.) Conduct Post-Test
(5 min.) Collect papers

At the beginning of each class, students were told that they were participating in a research experiment comparing different ways to teach and learn new English vocabulary words, and that their scores on any of the tests they were taking would not in any way affect their grade for the class. During the first class, students were given the Vocabulary Levels Test. The test took approximately 45 minutes to complete (plus another 15 minutes for handing out papers, giving directions, and collecting them), which left approximately 30 minutes to devote to usual classroom activities.
During the second class, students were first given the Yes-No Vocabulary pre-test, which took approximately 20 minutes to complete (including the time needed to give out the papers, give directions and collect the papers). Then, students were randomly given one of the four treatments, along with a list of the 10 new vocabulary words, with definitions given in both English and Japanese. In order to decrease the chance of copying, students sitting next to each other were given different treatments. The treatment tasks took approximately 30 minutes to complete (plus another 15 minutes for handing out papers, giving directions, and collecting them).

Immediately following the treatment, students were given the post-test vocabulary quiz, which took approximately 10 minutes to complete (plus another 10 minutes for handing out papers, giving directions, and collecting them).
There were two independent variables in this study. One independent variable was task type, which had four levels; a reading-based activity, a task-based activity, and two types of writing-based activities. The second independent variable was the overall vocabulary size of the learner, which had two levels: large or small. The dependent variable in the study was learning of the target words, which was operationalized as student score on a multiple choice vocabulary quiz given directly after the treatment.

Although the original number of subjects for this experiment was 122, a number of students had to be excluded from the analysis due to being absent during the day that either the Levels Test or the treatment was given (n=10). Also, cases where it was suspected that students were guessing were deleted (n=3). As in the pilot study, guessing was defined as instances where three or more (out of five) false positives appeared on a student’s Yes-Test. This left a group of 109 students.
A series of K-R20 analyses was conducted on all major instruments used in this study, in order to establish their reliability.

For the Levels Test, the K-R20 was calculated for the 109 subjects in this experiment, which resulted in a fairly high reliability figure of .82. Although somewhat lower than the reliability figures reported for the Read (1988) and Beglar and Hunt (1999) studies (.94 and .97, respectively) mentioned in the materials section, it is possible that the more homogeneous nature of this population, that of Japanese EFL college students with similar majors, was a contributing factor to the lower figure of .82.

The Yes/No test developed for this experiment consisted of 50 words including the 10 target words, 35 distractor words, and five non-words. A K-R20 analysis resulted in an overall test reliability of .86, with a reliability of .73 for the 10 target words.

The reliability of the post-treatment vocabulary quiz was also calculated using a K-R20 analysis, with a resulting figure of .68. This somewhat lower figure for the post-treatment vocabulary quiz can most likely be attributed to the far smaller number of items (n=10) as compared with the Levels Test and the Yes-No test (n=80, and n=50, respectively).
Comparison of Treatments

The first statistical procedure conducted in this study was a two-way analysis of variance (ANOVA), which was used to evaluate the effect of learner’s vocabulary size (created by categorizing their score on the Levels test). This analysis (Table 5), showed no significant interaction between treatment effect and vocabulary size ($p=.96$), however, both treatment ($p=.040$) and vocabulary size ($p=.0001$) had significant main effects. That is to say, the lack of significant interaction shows that the relative performance of the treatment is independent of vocabulary size.

Table 6 shows the results for the Fisher comparison of treatment one (reading), treatment two (activities), treatment three (writing) and treatment four (writing with
example sentences) with vocabulary size included. In the first column, each comparison of treatments is shown. The fourth column reveals which of the P-Values were significant. As seen in the one-way ANOVA, these multiple comparisons revealed that treatment one (reading) was significantly different from treatments two (activities) and three (writing). While a significant difference was found between treatments two and three in this analysis, the difference was not found to be significant in the one-way ANOVA presented above.

Figure 1 is a graphic display of the results for this comparison. The vertical axis displays the number of words learned, while the horizontal axis shows each of the four treatments: treatment one (reading), treatment two (activities), treatment three (writing) and treatment four (writing with example sentences). Line one represents learners with large vocabularies, line two, those with
medium-sized vocabularies, and line three, learners with small vocabularies. Results indicated that regardless of treatment, learners with larger vocabulary sizes consistently learned more words in each of the three treatments than learners with smaller vocabulary sizes.

Figure 1: Interaction Line Plot for Comparison of the Four Learning Conditions and Vocabulary Size

Next, a one-way analysis of variance (ANOVA) which compared the four treatments (learning conditions) with respect to the outcome variable (post-test score) was conducted in order to address the research question which
asked whether or not vocabulary learning activities that require pushed output would lead to the learning of more words than input or activity based tasks.

Table 7 presents the descriptive statistics for all measures in this analysis. Using a conventional but conservative alpha level of .001 the $z$ value for all data points must be under 3.30. The standard error of kurtosis was .469 using equation 4.6 from Tabachnick and Fidell (p. 72, 1996), giving a non-significant kurtosis value of .285 ($p < .001$). The standard error of skewness was approximately .235 according to equation 4.4 from Tabachnick and Fidell (p. 72, 1996), giving a significant kurtosis value of 4.102. While the ANOVA is said to be fairly robust with regard to deviations from the normal distribution of scores (p. 328, Hatch and Lazaraton, 1991), the negative skew of the scores works to suppress variance in the data, which may suppress significant differences between groups in this study. All other assumptions of ANOVA were met.

DISCUSSION

Summary of Main Results
This study investigated the effectiveness of two teaching techniques that are commonly used in the ESL classroom to teach new vocabulary words, that is via reading-based and activity-based tasks, and compares them with a third approach, via writing-based tasks. The results were fairly clear-cut.

Students learned significantly more new vocabulary words from the pushed-output technique (writing), than they did from either input or activity-based techniques, thus, the answers to research question one is affirmative. A secondary finding was that regardless of the method used, it is possible in even a relatively brief period of time, for learners to make substantial gains in their understanding of new vocabulary words.

The results of this study are also of significance to SLA theory. Although other studies have argued that depth of processing tasks would necessarily require longer amounts of time to complete (for example, see Laufer & Hulstijn, 2001), this study has shown that even when time on task was controlled, the task which required the deepest level of processing (writing original sentences), significantly outperformed the other conditions. Results thus support Craik and Lockhart’s (1972) Depth of Processing Theory for the population examined.
Despite the body of literature which suggests that vocabulary size is an important aspect of reading comprehension and academic performance (Hirsch & Nation, 1992; Laufer & Sim, 1985; Marshall & Gilmour 1993; Laufer 1992a & b), this study showed no significant differential effect for lexical size as to the effectiveness of the three techniques compared. As in the Swanborn and de Glopper study (2002) on the impact of reading purpose on incidental word learning, the current study found that learners with larger vocabulary sizes consistently learned more words than learners with smaller vocabulary sizes, providing indirect support for the importance of developing a large vocabulary. That is to say, the larger a student’s vocabulary size, the more words they are likely to learn irrespective of the technique used.

Another significant finding of this study relates to the amount of words students were able to learn in the input-based technique, the least effective of the four techniques compared. In a study by Zahar, Cobb, and Spada (2001), the authors claim that, based on both their own research, as well as a review of other L2 vocabulary reading studies, students can only be expected to learn an average of one out of 12-14 words that are encountered in typical reading tasks, with higher level learners (as measured by their score on the Levels Test) learning slightly more words than lower level learners.
In this experiment, however, students in the reading condition learned significantly more than Zahar, Cobb and Spada have hypothesized, with an average of 5/10 unknown target words correctly identified on the post treatment vocabulary quiz. The main difference, of course, is that the studies reviewed by Zahar, Cobb, and Spada were focused on incidental learning, whereas in this experiment the learning was much more explicit (since the definitions of the words were given out, and were underlined in the passage). The higher rate of learning then, may be further evidence that increases in attention leads to greater depth of processing and better retention of vocabulary words.

Another interesting finding in this experiment is with regard to the superior retention of words displayed in condition four (writing new words in sentences without example sentences). Although Swain has argued that pushed output not only needs to convey a message, but that it needs to be conveyed precisely, coherently, and appropriately, students in condition four achieved higher scores on their post tests (than the other three conditions) irrespective of whether the sentences they wrote were coherent, appropriate, or even correctly written. This held true when students made grammatical errors, spelling errors, errors in usage, and even in cases where students left whole sentences blank. It may be that the act of attempting to write new words in
original sentences required a level of processing so significantly deeper than the other conditions, that more information about the new words was retained even when the sentences were written incorrectly.

Pedagogic Recommendations

Although SLA research findings usually have classroom applications, they are not likely to be adapted by most teachers if the suggestions are time consuming ones that require a great deal of commitment, special tools (such as computers, video cameras, VCRs, etc.), or extra training. Most teachers are extremely busy people with little extra time in their schedule. Fortunately, one of the most obvious implications of this study, that assigning students the task of writing original sentences for new vocabulary words is more effective than developing controlled readings or word activity sheets for them, is actually an implication which greatly decreases the amount of preparation time needed when compared with more traditional approaches.

Another pedagogic implication of this study relates to the use of extensive reading as a means of increasing vocabulary size. As mentioned in the discussion section, students learned significantly more words in the reading condition than would be predicted by in the literature. This suggests that there may be pedagogic value in underlining,
defining, or otherwise drawing attention to target words in extensive reading passages. For example, if vocabulary learning were a secondary goal of a reading class, the results of this experiment suggest that a teacher would be able to greatly increase the chance that a word would be learned simply by drawing learners’ attention to it through simple techniques such as glossing, or underlining, again, tasks which don’t greatly increase the amount of preparation time needed.
CHAPTER 6
CONCLUSION

Suggestions for Future Research

Since the current experiment only looked at minor gains in vocabulary knowledge (passive retention) over a short period of time, one suggestion for a follow-up study be to conduct a longer-term experiment to track gains in the depth of vocabulary knowledge acquired over time by each of the methods. The preliminary results of the present research would predict that pushed-output techniques should lead students to greater gains in depth of knowledge of individual words over time, but that an intensive reading-based approached could lead to the learning of a greater number of words, albeit at a shallower depth.

Limitations

Several of the limitations to this study are ones common in the literature; the need for a larger n-size, the need to conduct similar experiments with different populations and proficiency levels, and the need to conduct delayed post-treatment tests (in order to look at long term retention rates for each of the three treatments).

One limitation specific to this experiment is the possibility that a “ceiling effect” may have hid significant
differences between the groups and a possible differential effect for vocabulary size. In other words, because so many students learned such a high number of the 10 treatment words in each of the four treatments, the results tended to cluster on the high end of the scale, making it difficult detect possible significant differences of treatment effects between the three groups. A subsequent experiment with a larger number of words, and more challenging tasks might reveal more significant results.

Concluding Comments

Until now, most evidence supporting Swain’s (1985) Pushed Output Hypothesis has been qualitative in nature. This study has added quantitative support for the effectiveness of pushed output in enhancing the second language acquisition process. Specifically, it has shown that vocabulary learning activities based on pushed output were more effective than more traditional approaches that used input or task-based approaches. It has also provided further support for Craik and Lockhart’s (1972) Depth of Processing Theory, by providing evidence that learning techniques which require deeper levels of processing lead to better learning, even when time on task is held constant.

In terms of pedagogy, it was found that the most effective technique for helping students to remember the
meaning of new vocabulary words is also one that requires very little extra preparation time - asking students to use the new words generatively, in original sentences. One classroom implication is that teachers who wish to increase their student’s receptive knowledge of new lexical items may be able to do so without taking away time from other classroom activities simply by giving students homework assignments to write new or key words in original sentences.

It should also be noted that although the reading-based approach was least effective in this particular experiment, students did make significant gains, and simple attention-getting devices such as underlining and highlighting seemed to greatly enhance the chance that a given word would be learned. Over longer periods of time, input-based approaches such as extensive reading do indeed seem to be effective in increasing learner’s vocabulary size.
